WHAT IS CLAIMED IS:

- An automatic gain control (AGC) apparatus comprising:
- 2 an analog variable gain amplifier;
- a digital variable gain amplifier coupled to an output of the analog variable gain

 4 amplifier; and
- a gain controller adapted to measure a signal output from the digital variable

 gain amplifier and to control the gains of the analog and digital variable gain amplifiers.
 - The apparatus of claim 1, further comprising:
- 2 a DC offset canceller interposed between the output of the analog variable gain amplifier and an input of the digital variable gain amplifier, wherein an AGC loop gain
- 4 is varied according to an operating mode of the DC offset canceller.
 - A method of operating an automatic gain control (AGC) loop in combination with a DC loop, comprising:
 - selecting a particular DC operating mode for the DC loop from among a plurality of possible DC operating modes:
- operating the DC loop in the selected DC operating mode to correct for DC 6 offset in a desired signal;
- selecting a particular AGC operating mode for the AGC loop from among a 8 plurality of possible AGC operating modes based on the selected DC operating mode; and
- 10 operating the AGC loop in the selected AGC operating mode to provide variable gain for the desired signal.
 - The method of claim 3, wherein the plurality of possible DC operating
 modes include an acquisition mode and a tracking mode.
 - The method of claim 4, wherein the acquisition mode has a wider loop
 bandwidth than that of the tracking mode and is used to more quickly remove a large
 DC offset in the desired signal.

Docket No: 010161 EJ 8313 91918 US

2

- The method of claim 3, wherein each of the plurality of possible AGC operating modes is associated with a respective AGC loop gain.
- The method of claim 3, wherein the plurality of possible AGC operating modes includes a normal mode and a low gain mode.
- The method of claim 7, wherein the plurality of possible AGC operating modes further include a freeze mode.
- The method of claim 4, wherein the selected AGC operating mode is a low gain mode when the selected DC operating mode is the acquisition mode.
- 2 10. The method of claim 4, wherein the selected AGC operating mode is a freeze mode when the selected DC operating mode is the acquisition mode.
- 2 11. A receiver unit in a wireless communication system, comprising:
- a DC loop configurable to operate in one of a plurality of possible DC operating
- 4 modes to correct for DC offset in a desired signal; and
- an automatic gain control (AGC) loop configurable to operate in one of a
- 6 plurality of possible AGC operating modes to provide variable gain for the desired signal, wherein the particular AGC operating mode to be used is determined based on
- 8 the particular DC operating mode selected for use for the DC loop.
- An control apparatus in a wireless communication system, comprising:
 means for selecting a particular DC operating mode for a DC loop from among a
- 4 plurality of possible DC operating modes;
- means for operating the DC loop in the selected DC operating mode to correct 6 for DC offset in a desired signal;

10

means for selecting a particular AGC operating mode for an automatic gain

8 control (AGC) loop from among a plurality of possible AGC operating modes based on
the selected DC operating mode; and

means for operating the AGC loop in the selected AGC operating mode to provide variable gain for the desired signal.

2 13. A method of operating a DC loop in a receiver unit, comprising:

selecting a particular operating mode for the DC loop from among a plurality of possible operating modes that include an acquisition mode; and

if the selected operating mode is the acquisition mode,

6 operating the DC loop in the acquisition mode for a particular time duration to correct for DC offset in a desired signal, wherein the particular time duration is

inversely proportional to a loop bandwidth for the DC loop for the acquisition mode, and

transitioning out of the acquisition mode after the particular time duration.

- 2 14. The method of claim 13, wherein the acquisition mode is selected in response to an event expected to result in a large DC offset in the desired signal.
- 2 15. The method of claim 14, wherein the event corresponds to a switch to new analog circuit stages to process the desired signal.
- 2 16. The method of claim 14, wherein the event corresponds to application of a new DC offset value to correct for static DC offset in the desired signal.
- The method of claim 13, wherein the plurality of possible operating modes further include a tracking mode.

10034734.182101

Docket No: 010161 EJ 8313 91918 US

- The method of claim 17, wherein the transition is made from the
 acquisition mode to the tracking mode after the particular time duration.
- 2 19. The method of claim 13, wherein the particular time duration is further selected based on an expected amplitude of the DC offset in the desired signal.
- The method of claim 13, wherein the particular time duration is further selected to minimize a combination of DC offset introduced in the desired signal and
 loop noise from the DC loop.
- A DC loop in a receiver unit, comprising:
- a summer operative to subtract a DC offset value from a desired signal to

 4 provide a DC offset corrected signal; and
- 4 provide a DC offset corrected signal; and
- a loop control unit configurable to operate in one of a plurality of possible

 6 operating modes to provide the DC offset value, wherein the plurality of possible
- operating modes include an acquisition mode having a particular loop bandwidth, and

 8 wherein the loop control unit is operated in the acquisition mode, when selected, for a
- particular time duration inversely proportional to the loop bandwidth for the acquisition
- 10 mode and to transition out of the acquisition mode after the particular time duration.
 - 2 22. An apparatus in a receiver unit, comprising:
 - means for selecting a particular operating mode for a DC loop from among a
- 4 plurality of possible operating modes that include an acquisition mode; and
- means for operating the DC loop in the acquisition mode for a particular time
- 6 duration, if the selected operating mode is the acquisition mode, to correct for DC offset in a desired signal, wherein the particular time duration is inversely proportional to a
- 8 loop bandwidth for the DC loop for the acquisition mode, and
- means for transitioning out of the acquisition mode after the particular time

- A method of digitally amplifying a desired signal, comprising:
- 2 receiving a gain represented in a logarithm format;
 - determining a difference between the received gain and a gain offset;
- 4 converting the difference, represented in the logarithm format, to an output gain represented in a linear format; and
- 6 digitally multiplying the desired signal with the output gain.
- 2 24. A digital variable gain amplifier (DVGA) comprising:
 - a first unit operative to receive a gain represented in a logarithm format and to
 - determine a difference between the received gain and a gain offset;
 - a second unit operative to convert the difference, represented in the logarithm
 - format, to an output gain represented in a linear format; and
 - a digital multiplier operative to multiply input samples with the output gain to
- 8 provide output data.

- 2 25. The DVGA of claim 24, further comprising:
- a multiplexer operative to multiplex inphase and quadrature input samples into a single sequence of samples, and wherein the digital multiplier is operative to multiply
- the inphase and quadrature input samples in a time-division multiplexed manner.
- An apparatus for digitally amplifying a desired signal, comprising: means for receiving a gain represented in a logarithm format;
- 4 means for determining a difference between the received gain and a gain offset; means for converting the difference, represented in the logarithm format, to an
- 6 output gain represented in a linear format; and
 - means for digitally multiplying the desired signal with the output gain.
- 2 27. A method of controlling one or more analog circuits via a serial bus, comprising:
- 4 receiving a control for a particular analog circuit;

Docket No: 010161 EJ 8313 91918 US

forming a message corresponding to the received control:

- 6 sending the message over the serial bus;
 - receiving the message at the particular analog circuit; and
- 8 adjusting one or more characteristics of the particular analog circuit based on the received message.
- 28. The method of claim 27, wherein the particular analog circuit is an amplifier configurable to operate at one of a plurality of discrete gains, and wherein the
 4 message is indicative of a specific discrete gain to be used for the amplifier.
- 2 29. The method of claim 27, wherein the message is used to adjust a bias current for the particular analog circuit.
- 2 30. The method of claim 27, wherein the message is used to adjust the frequency for a signal generated by the particular analog circuit.
- The method of claim 27, wherein each of the one or more analog circuits is assigned a respective priority, and wherein messages are sent to the one or more
- 4 analog circuits based in part on their assigned priorities.
- 2 32. The method of claim 27, wherein each of the one or more analog circuits is associated with a respective address.
- 2 33. An apparatus for controlling one or more analog circuits via a serial bus, comprising:
- 4 means for receiving a control for a particular analog circuit; means for forming a message corresponding to the received control;
- 6 means for sending the message over the serial bus;

Docket No: 010161 EL 8313 91918 US

means for receiving the message at the particular analog circuit; and means for adjusting one or more characteristics of the particular analog circuit based on the received message.

- 2 34. A receiver unit comprising:
- an RF front-end unit operative to amplify, downconvert, and digitize a received signal to provide samples;
- a digital signal processor operative to process the samples to provide output
- 6 data; and

8

- a serial bus interface (SBI) unit operative to provide controls for the RF front
 8 end unit via a serial bus.
- 2 35. The receiver unit of claim 34, wherein the SBI unit is configured to support a plurality of hardware request channels.
- 2 36. The receiver unit of claim 35, wherein each hardware request channel is associated with a respective priority.
- 2 37. The receiver unit of claim 35, wherein each hardware request channel is operable to send messages via a plurality of possible data transfer modes.
- 2 38. The receiver unit of claim 37, wherein the plurality of possible data transfer modes include a fast transfer mode and an interrupt transfer mode.
- 2 39. A method of processing a desired signal in a wireless communication system, comprising:
- 4 amplifying the desired signal with a first gain having a coarse resolution;

downconverting the amplified signal from radio frequency (RF) to baseband 6 with a single frequency downconversion stage;

digitizing the downconverted signal to provide samples; and

- 8 digitally amplifying the samples with a second gain having a fine resolution to provide output data having a desired signal amplitude.
 - 40. The method of claim 39, further comprising:
- 2 correcting for DC offset in the samples with a DC loop, wherein the DC offset corrected samples are digitally amplified.
 - 41. A direct downconversion receiver comprising:
- 2 an RF front-end unit operative to amplify, downconvert, and digitize a received signal to provide samples;
- 4 a digital variable gain amplifier (DVGA) operative to amplify the samples with a first gain to provide output data having a desired signal amplitude; and
- 6 an automatic gain control (AGC) loop operative to provide the first gain for the DVGA based in part on the output data.
 - 42. The direct downconversion receiver of claim 40, further comprising:
- 2 a DC offset canceller operative to correct for DC offset in the samples, and wherein the DVGA is operative to amplify the DC offset corrected samples.
- 43. The direct downconversion receiver of claim 40, wherein the AGC loop

 2 is further operative to provide a second gain for the RF front-end unit.
 - 44. An apparatus in a wireless communication system, comprising:
- 2 first means for amplifying a received signal;
 - means for canceling a DC offset in the amplified signal;
- 4 second means for digitally amplifying the DC offset cancelled signal; and means for measuring the digitally amplified signal and to control the gains of the
- 6 first and second amplifying means.
 - 45. A receiver unit comprising:
- 2 an analog variable gain amplifier;

Docket No: 010161 EJ 8313 91918 US

- a DC offset canceller coupled to an output of the analog variable gain amplifier:
- 4 a digital variable gain amplifier coupled to an output of the DC offset canceller;
- a gain controller adapted to measure a signal output from the digital variable

 6 gain amplifier and to control the gains of the analog and digital variable gain amplifiers;

 and
- 8 a serial bus interface (SBI) unit operative to provide the gain for the analog variable gain amplifier via a serial bus.

A receiver unit comprising:

- an RF front-end unit operative to amplify, downconvert, and digitize a received signal to provide samples;
- 4 a DC loop operative to cancel DC offset in the samples;
- a digital variable gain amplifier (DVGA) operative to amplify the DC offset 6 canceled samples with a first gain to provide output data having a desired signal amplitude;
- an automatic gain control (AGC) loop operative to provide the first gain for the DVGA and a second gain for the RF front-end unit based in part on the output data; and
- 10 a serial bus interface (SBI) unit operative to provide the second gain to the RF front-end unit.
